Revised: 10/5/2019/Rev 1

Executive Summary

Development Standards & Practices Used

- Electrical simulations
- PCB design software
- Testing equipment: Oscilloscopes, Multimeters, Power supply, function generators
- PCB machining

Summary of Requirements

- Footprint smaller than 3.5" X 2"
- Final Product must deliver consistent results
- Developed on high end PCB
- Generate magnetic flux density of 500 Gauss
- Must have a rise time of 100 ns or less
- MO material must fit securely inside coil
- Must have an SMA connector attached

New Skills/Knowledge acquired that was not taught in courses

Before going into this project none of the group members knew much about MO or Magneto Optic materials. This required a little bit of research into how they worked so we could get a better understanding of what our project was trying to accomplish. We also had to investigate the concept of Faraday rotation. This went along with our research on MO materials because Faraday rotation is what causes the change of light using a magnetic field.

None of us have ever created our own PCB using a machine so this required training on our part. Obviously, the PCB's used in our final product will be professionally made but for testing and prototyping purposes these PCB's will work.

1 Introduction

1.1 ACKNOWLEDGEMENT

We would like to thank the following individuals for assisting us throughout this project. Doctor Mani Mina and Wei Shen Theh. Doctor Mina is the creator of the project and provides us with the space and materials we need to work on our project. Wei Shen is very knowledgeable about the project and has provided us continuous advice and information.

1.2 PROBLEM AND PROJECT STATEMENT

The goal of this project is to create a high-speed magnetic field generator with a magnetic flux density of 500 Gauss with a rise time of less than 100 ns. This generator will be used with electrical equipment such as network speed solutions and medical equipment. Our proposal is to create a small PCB that can fit in this type of equipment while still completing the tasks stated above. We need to be able to fit a MO material inside of the coil as well. This project has great potential to speed up a lot of optic cable applications. Rather than using only the speed of electrons to process information, we can use the generator along with the MO material to bend the light and process signals quicker. By the end of this project we hope to have a small circuit board that (when powered) completes the above requirements.

1.3 OPERATIONAL ENVIRONMENT

Our product is not planned to be used in any harsh environment. The only sort of environment we need to worry about is an electrically noisy one. If there is other machinery in the room where it is being used, we need to make sure it will not interfere with our product.

1.4 REQUIREMENTS

1. The product will generate a magnetic flux density of at least 500 Gauss
2. The product will have a rise time of 100 ns or less.
3. The pulse generated by the product must be able to be controlled.
4. The product will be less than or equal to 3.5" X 2"

1.5 INTENDED USERS AND USES

The use of this product will be in addition to existing products. The intended immediate users will be companies that create medical or routing equipment and need this product to add to their product. Secondary consumers will be those that use the equipment that our product has been added to.

1.6 ASSUMPTIONS AND LIMITATIONS

Assumptions: This product will be used inside other equipment. This product will not be used in any harsh environment.

Limitations: The product must generate 500 Gauss to be able to correctly change the MO material. The product must have a rise time of less than or equal to 100 ns. The product will be powered by an external power supply.

1.7 EXPECTED END PRODUCT AND DELIVERABLES

These tie in with the goals. What deliverables are necessary to meet the goals outlined in the introduction?

List the end product and any other items, along with a brief description, that will be delivered to the client prior to the end of the project.

- If the end product is to be commercialized, the description shall be of the commercialized end product.
- It shall be in the form of a technical product announcement, as opposed to a product advertisement, and shall not include a list of technical specifications.
- Any other items that will be delivered to the client shall also be included and described unless their definition and description are obvious.
- Examples might include a household power supply to eliminate the need for batteries, a user's manual, or other project reports.
- There shall be at least a one-paragraph description for each item to be delivered.
- Delivery dates shall also be specified.

The end product will be a PCB with a coil that can generate a magnetic flux density of 500 gauss with a rise time of 100 ns. The product will be laid out on a professionally made PCB with an SMA connector. A datasheet will be included with the product showing input and output specifications as well as dimensions of parts for proper integration into other machinery. This product is not meant to be used in harsh environments and must be used to specified purposes.

2. Specifications and Analysis

2.1 PROPOSED DESIGN

There is currently one primary design that will most likely be the one used. It is a design which was given to us by the TA's and it needs to be perfected. We will need to test and measure many of its impedances to see what kind of parasitics we are working with. By doing so, we will try to minimize those parasitics and increase maximum rise time of the voltage in the inductor which generates the Gauss field.

We have also been looking into changing the given design completely. Currently a MOSFET is being used to drive the coil, but we want to go back a few steps and possibly redesign this idea. Possibly using other technology that will allow us for faster slew rates than those of MOSFETs.

2.2 DESIGN ANALYSIS

So far It has been mostly research and defining our requirements. The biggest problem we have encountered is not that we don't know how to design circuits, or how to manufactory them; the problem is that we did not understand the overall goal of the project and how to reach it.

Currently, after we had talks with our clients, we have understood our requirements and we know how to proceed with circuit designing. Our requirements are as follow:

- Achieve ~500 Gauss Electric Field within a coil
- Input one pulse with minimum 100nS rise time

Looking at these specified requirements, we were led to believe that the MOSFETs that are currently being used might not be the best way to go. There could be an IC chip or an OP amp that is able to do the same job as the MOSFET, but faster.

2.3 DEVELOPMENT PROCESS

The development process we are following is different than the usual processes. Our process is used to improve the currently used design and to make it faster by decreasing parasitic.

If we were to stick with this current design, our process would be to redesign the parasitic, build, and test the circuit. Then continue this cycle until the results we want are achieved.

If we want to design a new method of driving the coil other than using a MOSFET, we will need to follow a new set of directions. First, we will need to research the possible ways of driving the coil, then look for ways to implement the new items. And lastly, we will need to design board and test them. This will be a much longer process than the previous.

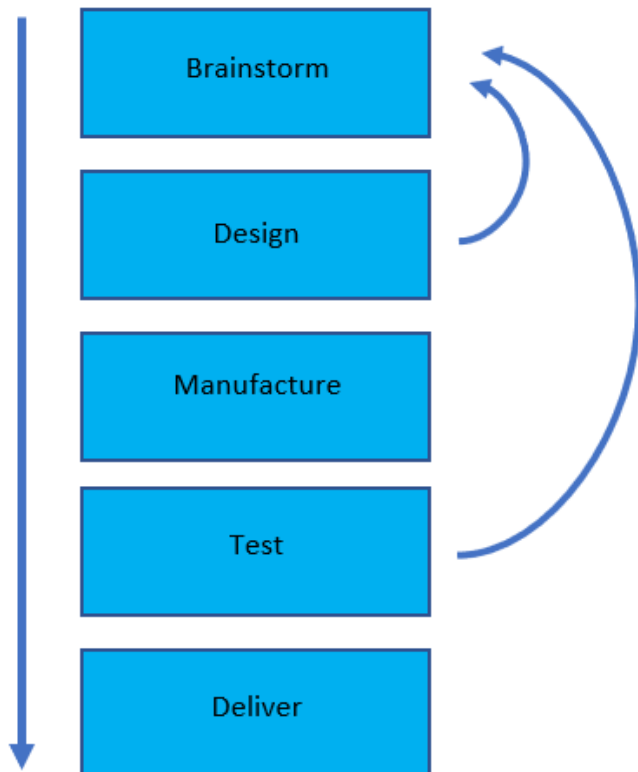

2.4 DESIGN PLAN

As previously discussed, there are two separate design plans that we can follow.

For basic MOSFET use, this flow chart will be used:

For a new design which does not include a MOSFET. New ideas and fixes will have to be constantly made:

3. Statement of Work

3.1 PREVIOUS WORK AND LITERATURE

This project is a continuation of a few years of past senior design projects. The team from the previous year was tasked with developing a system that created a 500 Gauss field with a rise time of 100 ns. The advantages to work previously done on this project has provided us with a working circuit that generates a magnetic flux density of 433 Gauss with a rise time of 111 ns. While this helps in cutting our design work, we do need to find alternative solutions to aid in keeping the magnetic flux density around 500 Gauss as is but bring down the rise time.

Future research topics and references will be discussed here.

3.2 TECHNOLOGY CONSIDERATIONS

- Alternative semiconductors with different R_s and gate Cap values.
 - Other MOSFETS may prove to be more efficient than current MOS in design. Looking to reduce gate cap and alternative R_s value.
- GaN MOSFETS
 - Determine if rise time is better than current MOS being used.
- Gate amplifiers
 - Possible replacement to current MOS to aid in overall rise time; may add more delay.
- Alternative Inductors
 - Test possible alternatives that aid in higher current values.
- Alternative Capacitors
 - Possibly aid cutting down overall rise time by altering layout/composition.

3.3 TASK DECOMPOSITION

- Zack Higgs - Team Lead
 - Maintain and schedule communication between members and external sources.
 - Manage and maintain meetings between members and stakeholders.
- Jason Cheng - Technology Lead
 - Develop and maintain PCBs and schematics.
 - Aid in creating of hardware.
 - Design and maintain team website and a consistent update of project.
- Craig Philipp - Communication and Presentation Lead
 - Develops and manages presentations.
 - Verify work is making progress for project.
 - Oversees individual and team reports.
- Ben Colson - Test Engineer Lead

- Verify working and in progress circuits.
 - Creates plans for testing and verification.
 - Documents and organizes testing sessions for verifying functionality of circuits.
- Harel Cohen - Hardware Lead
 - Verifies hardware is ordered and any/all parts are accounted for.
 - Verifies all PCBs are accounted for and ready for testing.
 - Works with tech lead between revisions to organize prototypes and any updates.

3.4 POSSIBLE RISKS AND RISK MANAGEMENT

- Costs
 - Currently not concerned with the costs of overall project.
- Materials
 - Only concern pertains to obtaining parts in house to populate any physical prototypes.
 - If parts are not directly available, we will need to order the proper hardware and wait for its arrival for proper testing.
- Equipment
 - Training for use of Coover equipment.
 - This will hinder any physical prototypes being developed if access and proper training with equipment is not met.
- Knowledge
 - Need to obtain good understanding of overall project to ensure we have forward momentum with project.
 - Possible meetings with subject matter experts need to be scheduled to ensure we can have their knowledge to aid in possible improvements and understanding of the project.

3.5 PROJECT PROPOSED MILESTONES AND EVALUATION CRITERIA

- Developed system performs with a sub 100ns rise time and generates a magnetic flux density with amplitude 500 Gauss.
- Develop working and testable Prototypes.
- Test prototypes to confirm and progress of rise time, and if not, what can be altered.
- Have consistent forward progress with design.

3.6 PROJECT TRACKING PROCEDURES

To ensure tracking of overall progress, the team will have consistent weekly meetings. These meetings will contain time for individual progress reports and reflections. Concluding these meetings, the team will determine if progress is being made and decided everyone's next step for the week. If no progress was made, we determine the cause of this and reflect on how to ensure forward momentum is sustained.

3.7 EXPECTED RESULTS AND VALIDATION

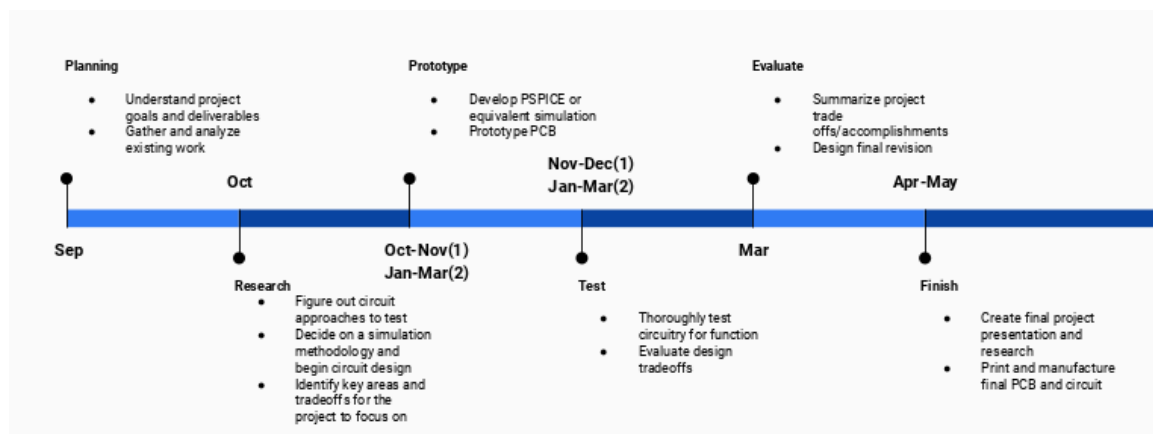

Desired Outcome:

- Design and test a working system that generates a flux density of amplitude 500 Gauss with a sub 100 ns rise time.

To ensure that solution to the design works, we will develop a working and testable prototype. This prototype will then be tested in its simulated environment.

4. Project Timeline, Estimated Resources, and Challenges

4.1 PROJECT TIMELINE

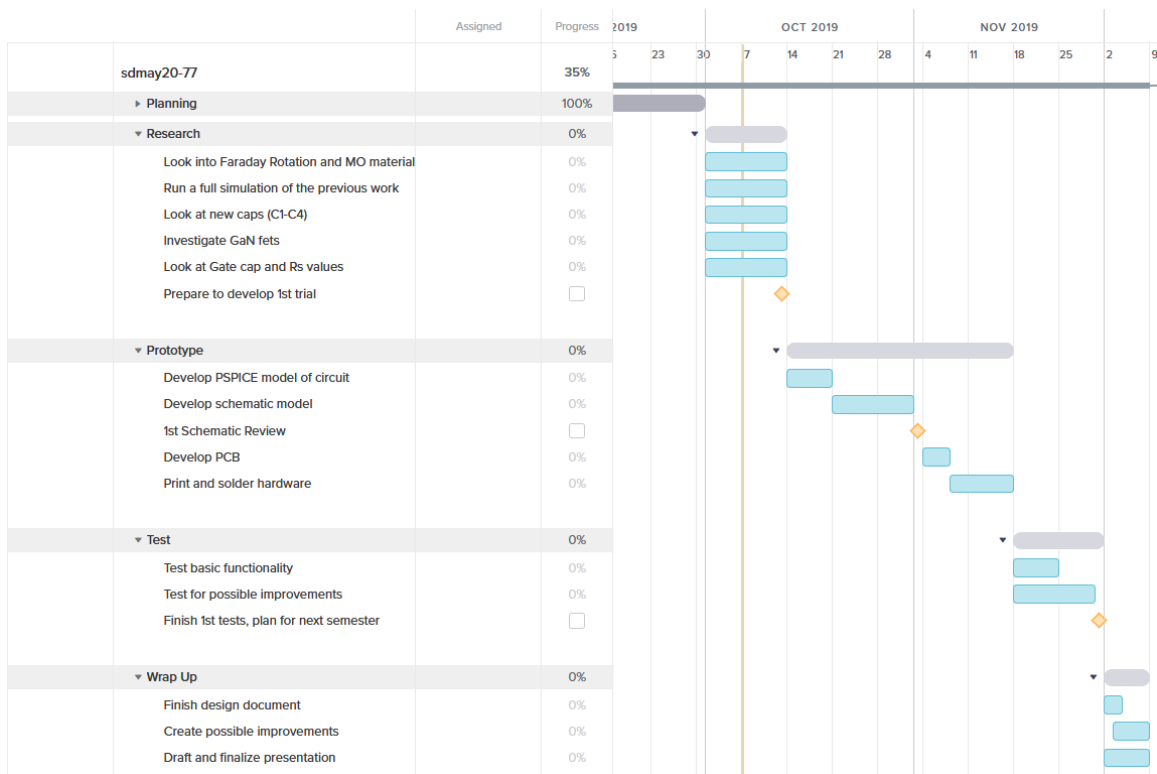

4.2 FEASIBILITY ASSESSMENT

The project will be a circuit in the form of a PCB to generate a magnetic field for use in fiber optics. This project will iterate on previous designs, attempting to get a working circuit that meets minimum requirements necessary to be implemented in the full project. This will involve many iterations of the circuit, trying to find an ideal balance, both virtual and physical.

Problems will occur throughout the project. The project will involve iterating on a circuit and implementing parts that will have various tradeoffs. This will eventually lead to a group discussion over what tradeoffs have to be made, and how to make them. In addition, as we get more advanced with the prototypes, it will be difficult to advance with our knowledge, so external resources will have to be consulted. The group must make sure to reach out to Dr. Mina, the group's sponsor, Wei-Shen, and other experts to understand and verify our understanding of the circuit, and the effects we will be having.

4.3 PERSONNEL EFFORT REQUIREMENTS

Each group member will be assigned an amount of responsibility as close to equal as they can manage. Each task currently noted below will be assigned accordingly.

4.4 OTHER RESOURCE REQUIREMENTS

- Machine shop access for the PCB prototypes
- PSPICE simulation software
- Altium Designer or equivalent to design schematics and PCBs

4.5 FINANCIAL REQUIREMENTS

- ~\$500 - Parts related to PCB and tests
- ~\$100 - PCBs to test

5. Testing and Implementation

5.1 INTERFACE SPECIFICATIONS

Our first testing tool is a software simulation tool called PSPICE. This simulation tool allows us to model our circuit's behavior to given inputs. In PSPICE, we can import non-ideal models for all components allowing us to predict how to circuit will behave in actual tests. Two of our main goal for this project is to design a circuit that can switch on a coil with a rise time of 100ns and produce a field of 500 gauss. PSPICE allows us to predict these specifications and verify that the circuit should theoretically satisfy our criteria.

After fabricating our circuit one of our first tests will be to measure the magnetic field of our coil. This is to meet our first requirement, of having a magnetic field of 500 gauss within our coil. One initial hardware interface we will be using is a multimeter to measure voltage across our current sense resistor. This is our 0.05-ohm current sense resistor.

Our group will also be using an oscilloscope to view the signal traces of the coil. Using this tool, we can verify that our rise time is less than or equal to 100 ns. An oscilloscope will also allow us to see the quality of the pulse. In the past, we have seen ringing on this line, and we should be able to view this on the oscilloscope.

5.2 HARDWARE AND SOFTWARE

PSPICE:

PSPICE will be used to simulate the whole circuit and theoretically verify that all design specifications are met.

Advanced Design System (ADS):

Used to analyze the parameters of our circuit and to model the loss.

Multimeter:

This hardware tool will be used to measure supply voltages, check resistances, and read our current sense resistor

Oscilloscope:

The oscilloscope will be used to experimentally measure the rise time and signal integrity of the circuit. We will measure the rise time to verify that it is 100ns or less.

5.3 FUNCTIONAL TESTING

Our functional test will require using both a multimeter and oscilloscope to verify our rise time and magnetic field. We will read the voltage over our current sense resistor, using ohm's law we can find the current through our inductor. Because devices in series have equal current, we can find our current coil by measuring the voltage over our 0.05 ohm current sense resistor. By knowing the current through the inductor, we can then find the magnetic field of the inductor. The magnetic field (B field) in an inductor: where μ_0 is the permeability of free space, N is the turn density, I is the current through the solenoid.

$$B = \mu_0 NI$$

Using these three values we can experimentally calculate the magnetic field within our solenoid to verify that it is at least 500 gauss.

To experimentally verify the rise time of the coil, we need to use an oscilloscope. Using an oscilloscope, we can view voltage vs. time, and plot the voltage of the inductor to verify that it reaches its correct value in less than 100ns. We will capture traces on the oscilloscope using the cursors to mark change in time.

5.4 NON-FUNCTIONAL TESTING

After we receive our printed circuit boards (PCBs) we can test for power efficiency, size form factor, and compatibility with our magneto optic-material. We will also be looking to reduce any ringing on the signal which might not affect any functional tests immediately but might affect long term usability.

5.5 PROCESS

At this stage in our testing we are running simulations to test different types of MOSFETS, inductor values, and voltage levels. We are changing each of these to reduce the rise time and increase the magnetic field within the inductor. The goal of these tests is to reduce the inductance of the solenoid, resulting in a reduction in rise time. To reduce the inductance of the solenoid the number of turns of the inductor has to be reduced, resulting in a weaker magnetic field. Our hypothesis is that by increasing the supply voltage, the magnetic field and in result the current, will increase. The next step after successfully testing different MOSFETs, is to print PCBs and compare our theoretical results with our experimental results.

5.6 RESULTS

From the basic modeling and simulations using PSpice we found our circuit to have a rise time of around 47ns, with one non ideal component. We use the CSD17322Q5A MOSFET first, this has a gate capacitance of 570 pF. Because of the gate capacitance, there is a delay between the green trace and the red, inductor voltage.

Figure 1 - Red trace: V over resistor with rise time = 47ns, Green trace: V of gate pulse

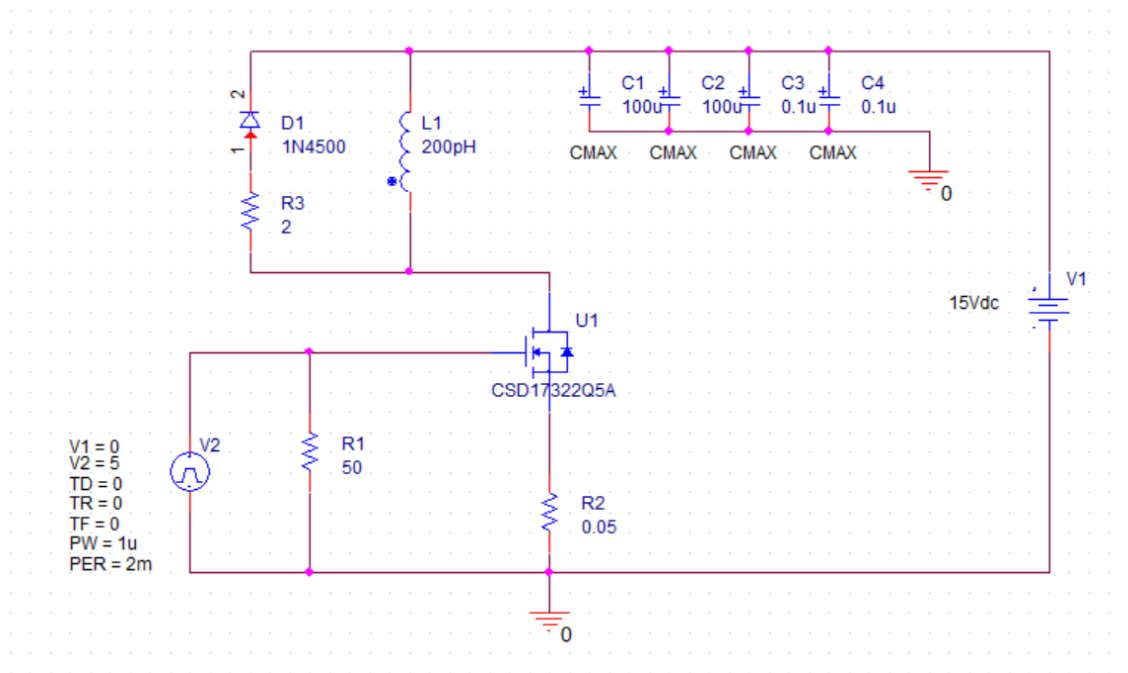

Figure 2 - PSPICE Simulation Circuit

This is a good start, but next we will be simulating other MOSFETS with different R_{ds} and gate capacitances. This will allow us to observe how these two parameters change the rise time and the current through the inductor, two of our biggest factories. We also will put in non-ideal components for the inductor, diode, capacitors, and resistors that model their effects at different frequencies and total parasitic losses. We also will be looking at printing our PCBs soon to do some experimental testing. This will allow us to compare our theoretical results to our experimental data. We want the PCBs as soon as possible so that if our theoretical data is flawed, we can correct for it in our simulation and fix the problem.

There have been a few issues finding all the simulation modes of all the MOSFETS and diodes we want to try. Each one is made by a different company and not all the component's simulation files are downloadable online. We will be contacting the companies to request a PSCIE simulation file.

6. Closing Material

6.1 CONCLUSION

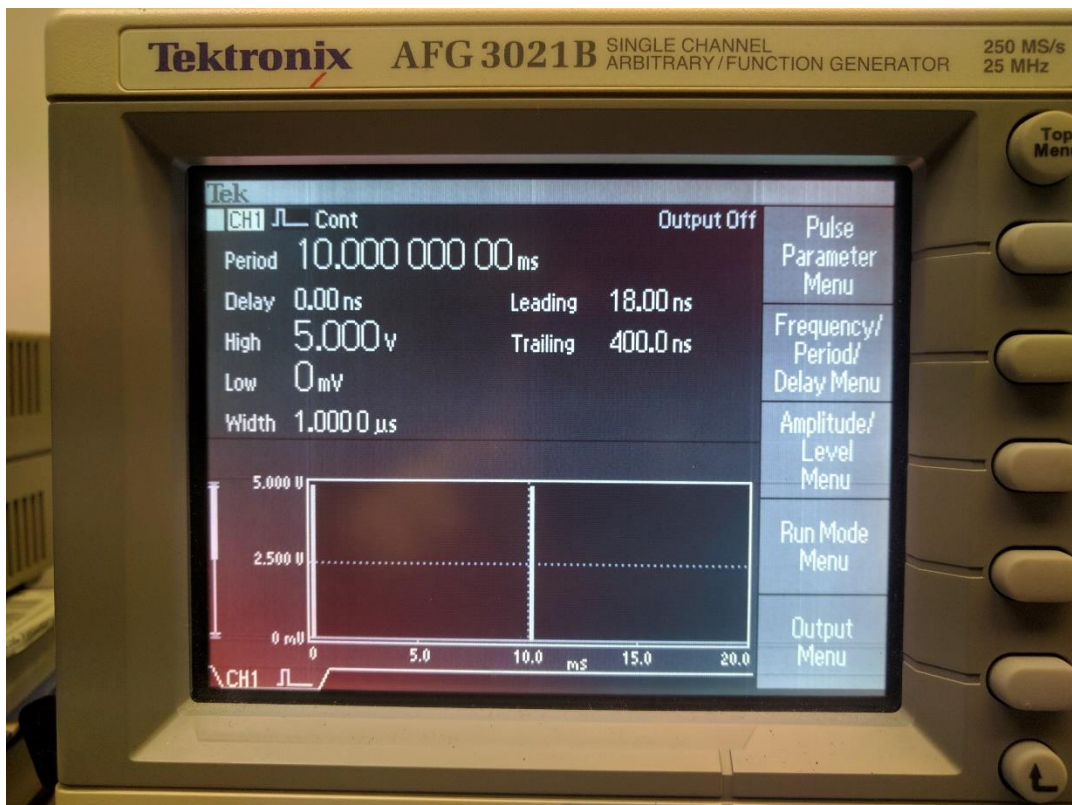

We have talked to the client and figured out the uses for our product. Based on the information we have received, we conducted research based on past projects. We also have done outside research to understand our project better such as the concept of Faraday Rotation and MO material research. Using this newly acquired information we started looking into ways we can improve our product to make the rise time faster than previous projects had made it.

Our plan is to continue to conduct research into different types of MOSFETs with different values of input and output capacitance so that we can continue to reduce our rise time while still holding our 500-gauss threshold. We have created a timeline and plan to stick to it so we can have a finished product at the end of this cycle. We found no drastic changes that should be made to the circuit besides finding parts that have better specifications that we are looking for.
